

\*The data are from a prospective study on body fat accretion in a cohort of 162 girls from the MIT Growth and Development Study. The study examined changes in percent body fat before and after menarche. The data represent a subset of the study materials and should not be used to draw substantive conclusions.

4	1	20.9443	0.53017	565	0.05	19.9029	21.9856	2.2857	1.97969	2.79848	0.31786	0.31699
5	1	21.4846	0.56147	565	0.05	20.3818	22.5874	-10.9646	-2.56764	-1.90242	-1.48193	-1.47768

\*Now let's plot the studentized residuals by time relative to menarche to view any patterns;

\*First, we'll create a loess smooth plot;

```
proc loess data=BF_pred plots=none;
  ods output outputstatistics=out_BF_pred;
  model StudentResid=Time_r_men;
run;
```

```
proc sort data=out_BF_pred;
  by Time_r_men DepVar;
run;
```

\*Now we'll view the loess smooth line by the actual values;

```
proc sgplot data=out_BF_pred;
  scatter x=Time_r_men y=DepVar/ markerattrs=(color=black size=5) ;
  series x=Time_r_men y=pred/ lineattrs=(color=blue thickness=5) ;
run;
```

```

*Lastly let's check the normality of the residuals using the scaled version;
proc univariate data=BF_pred2 normal;
var ScaledResid;
histogram ScaledResid;
qqplot ScaledResid;
run;

```

;

```
run;
```

\*A quick note on the "iter" command. It is the maximum number of additional iterations PROC MIXED performs to update the fixed effects and covariance parameter estimates following data point removal. When  $n > 0$ , the influence analysis is iterative. The default is  $n = 0$ . If  $n > 0$  and METHOD=REML (default) or METHOD=ML, the procedure updates fixed effects and variance-covariance parameters after removing the selected observations with additional Newton-Raphson iterations, starting from the converged estimates for the entire data. The process stops for each observation or set of observations if the convergence criterion is satisfied or the number of further iterations exceeds  $n$ ;

```
